Introduction to Reinforcement Learning

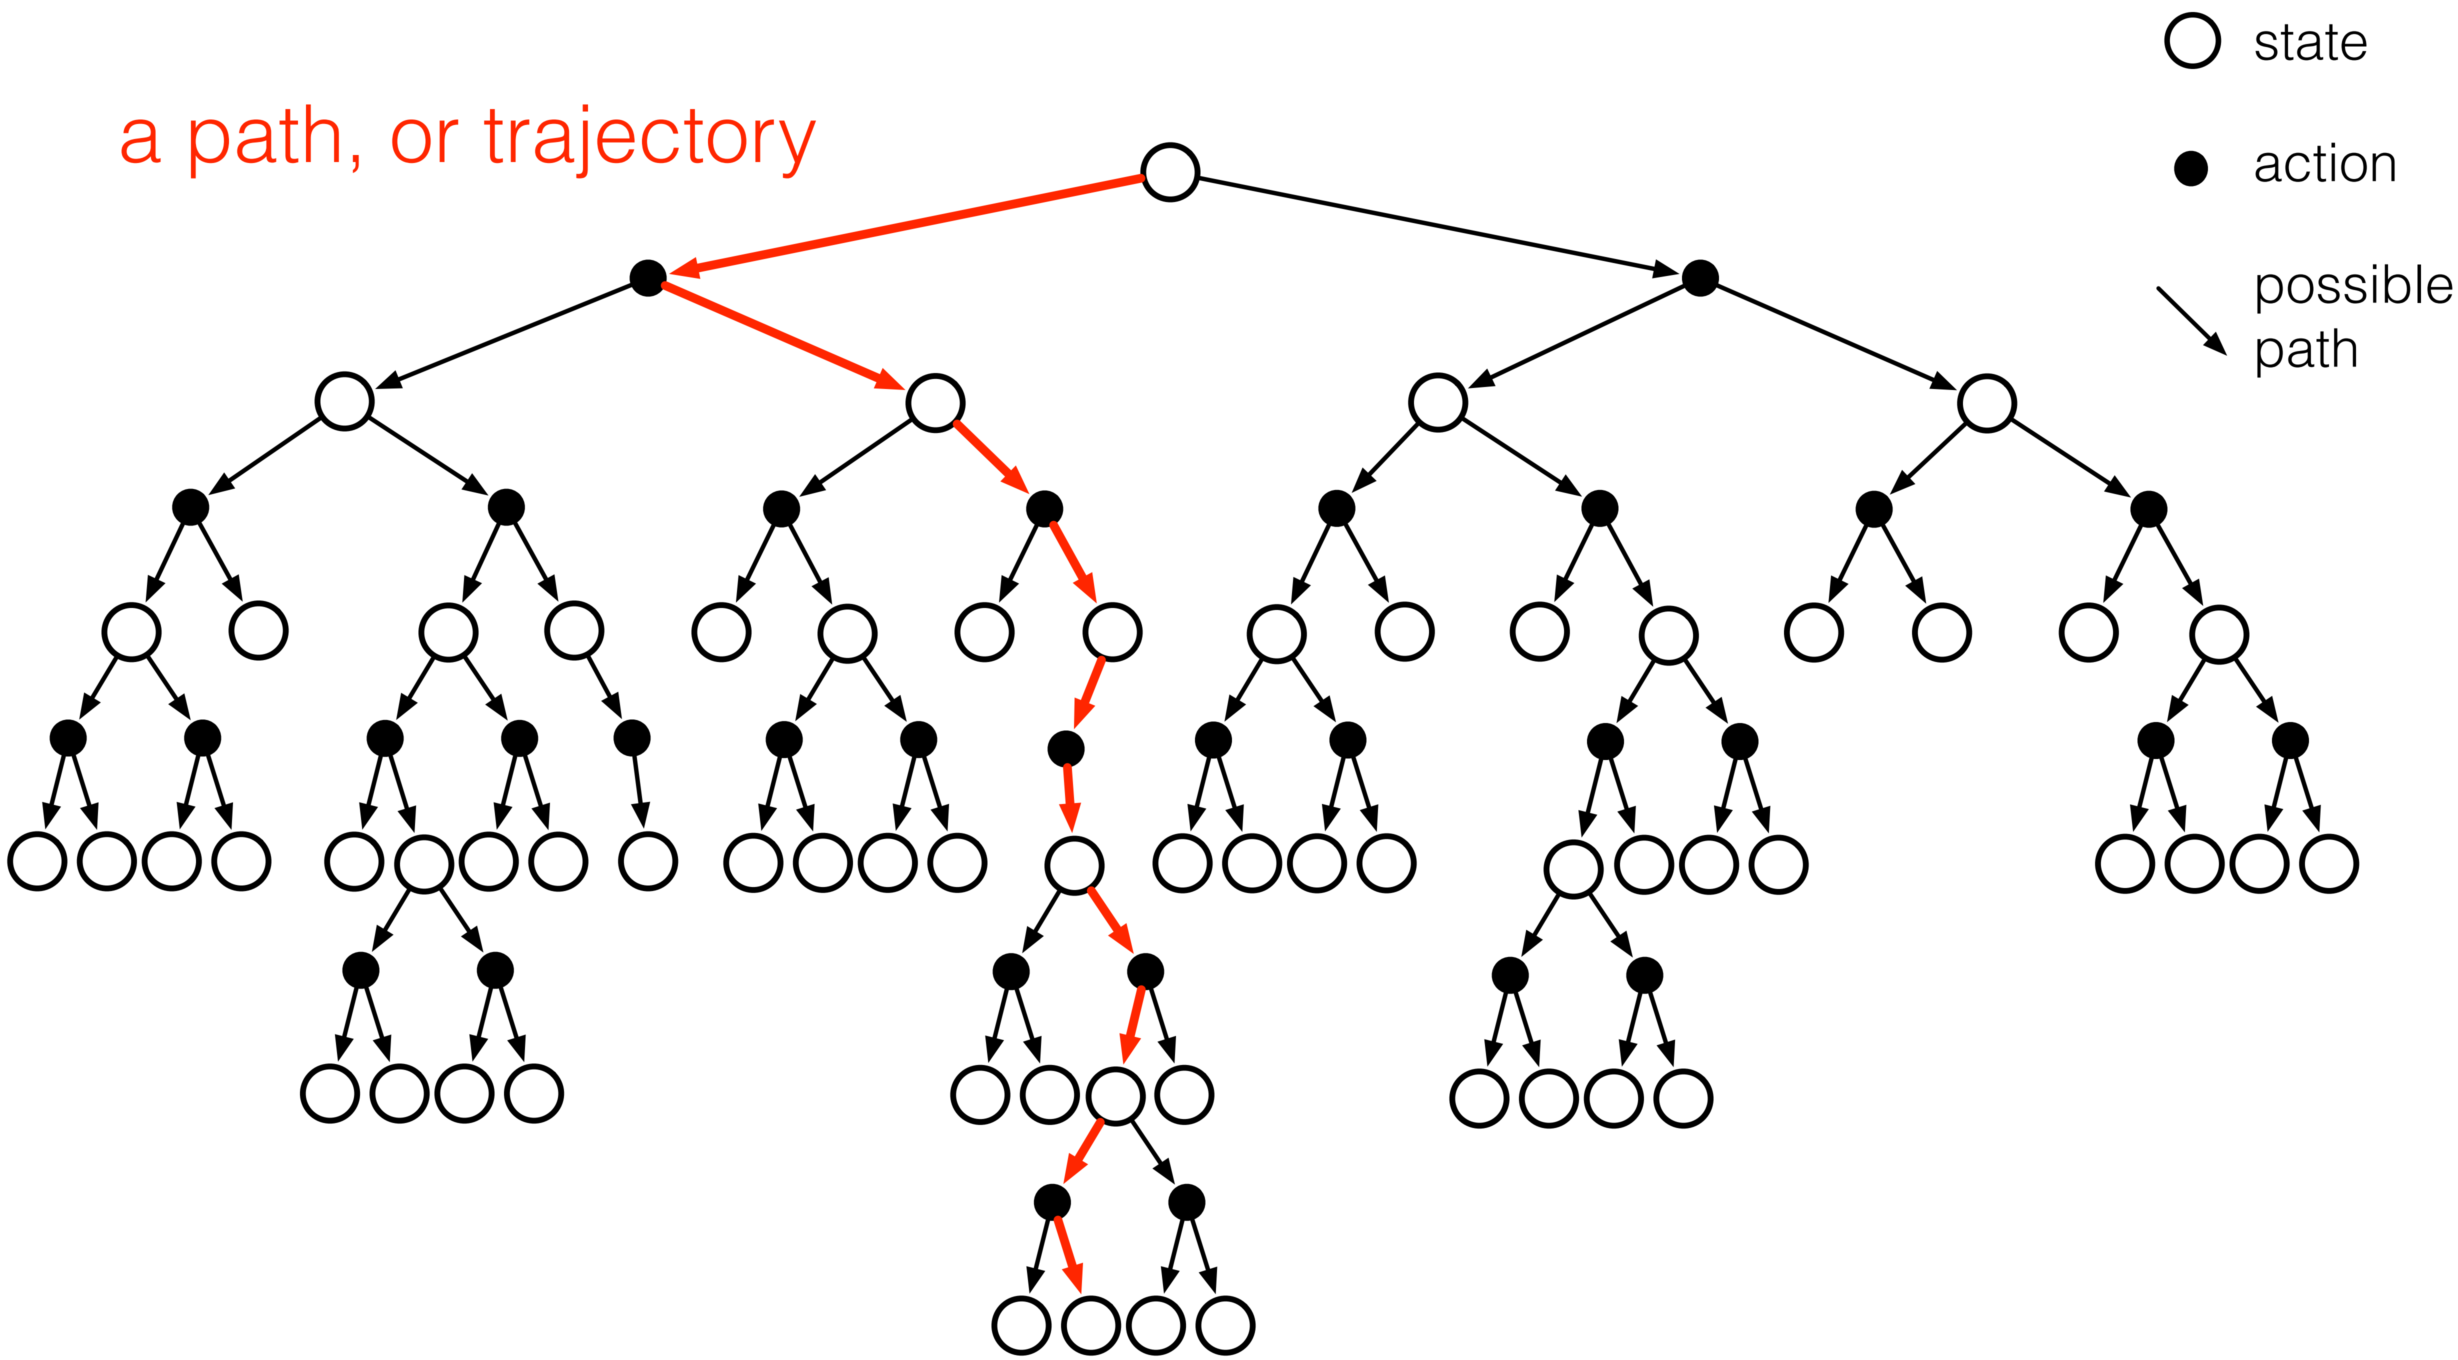
Part 6: Core Theory II:

Bellman Equations and Dynamic Programming

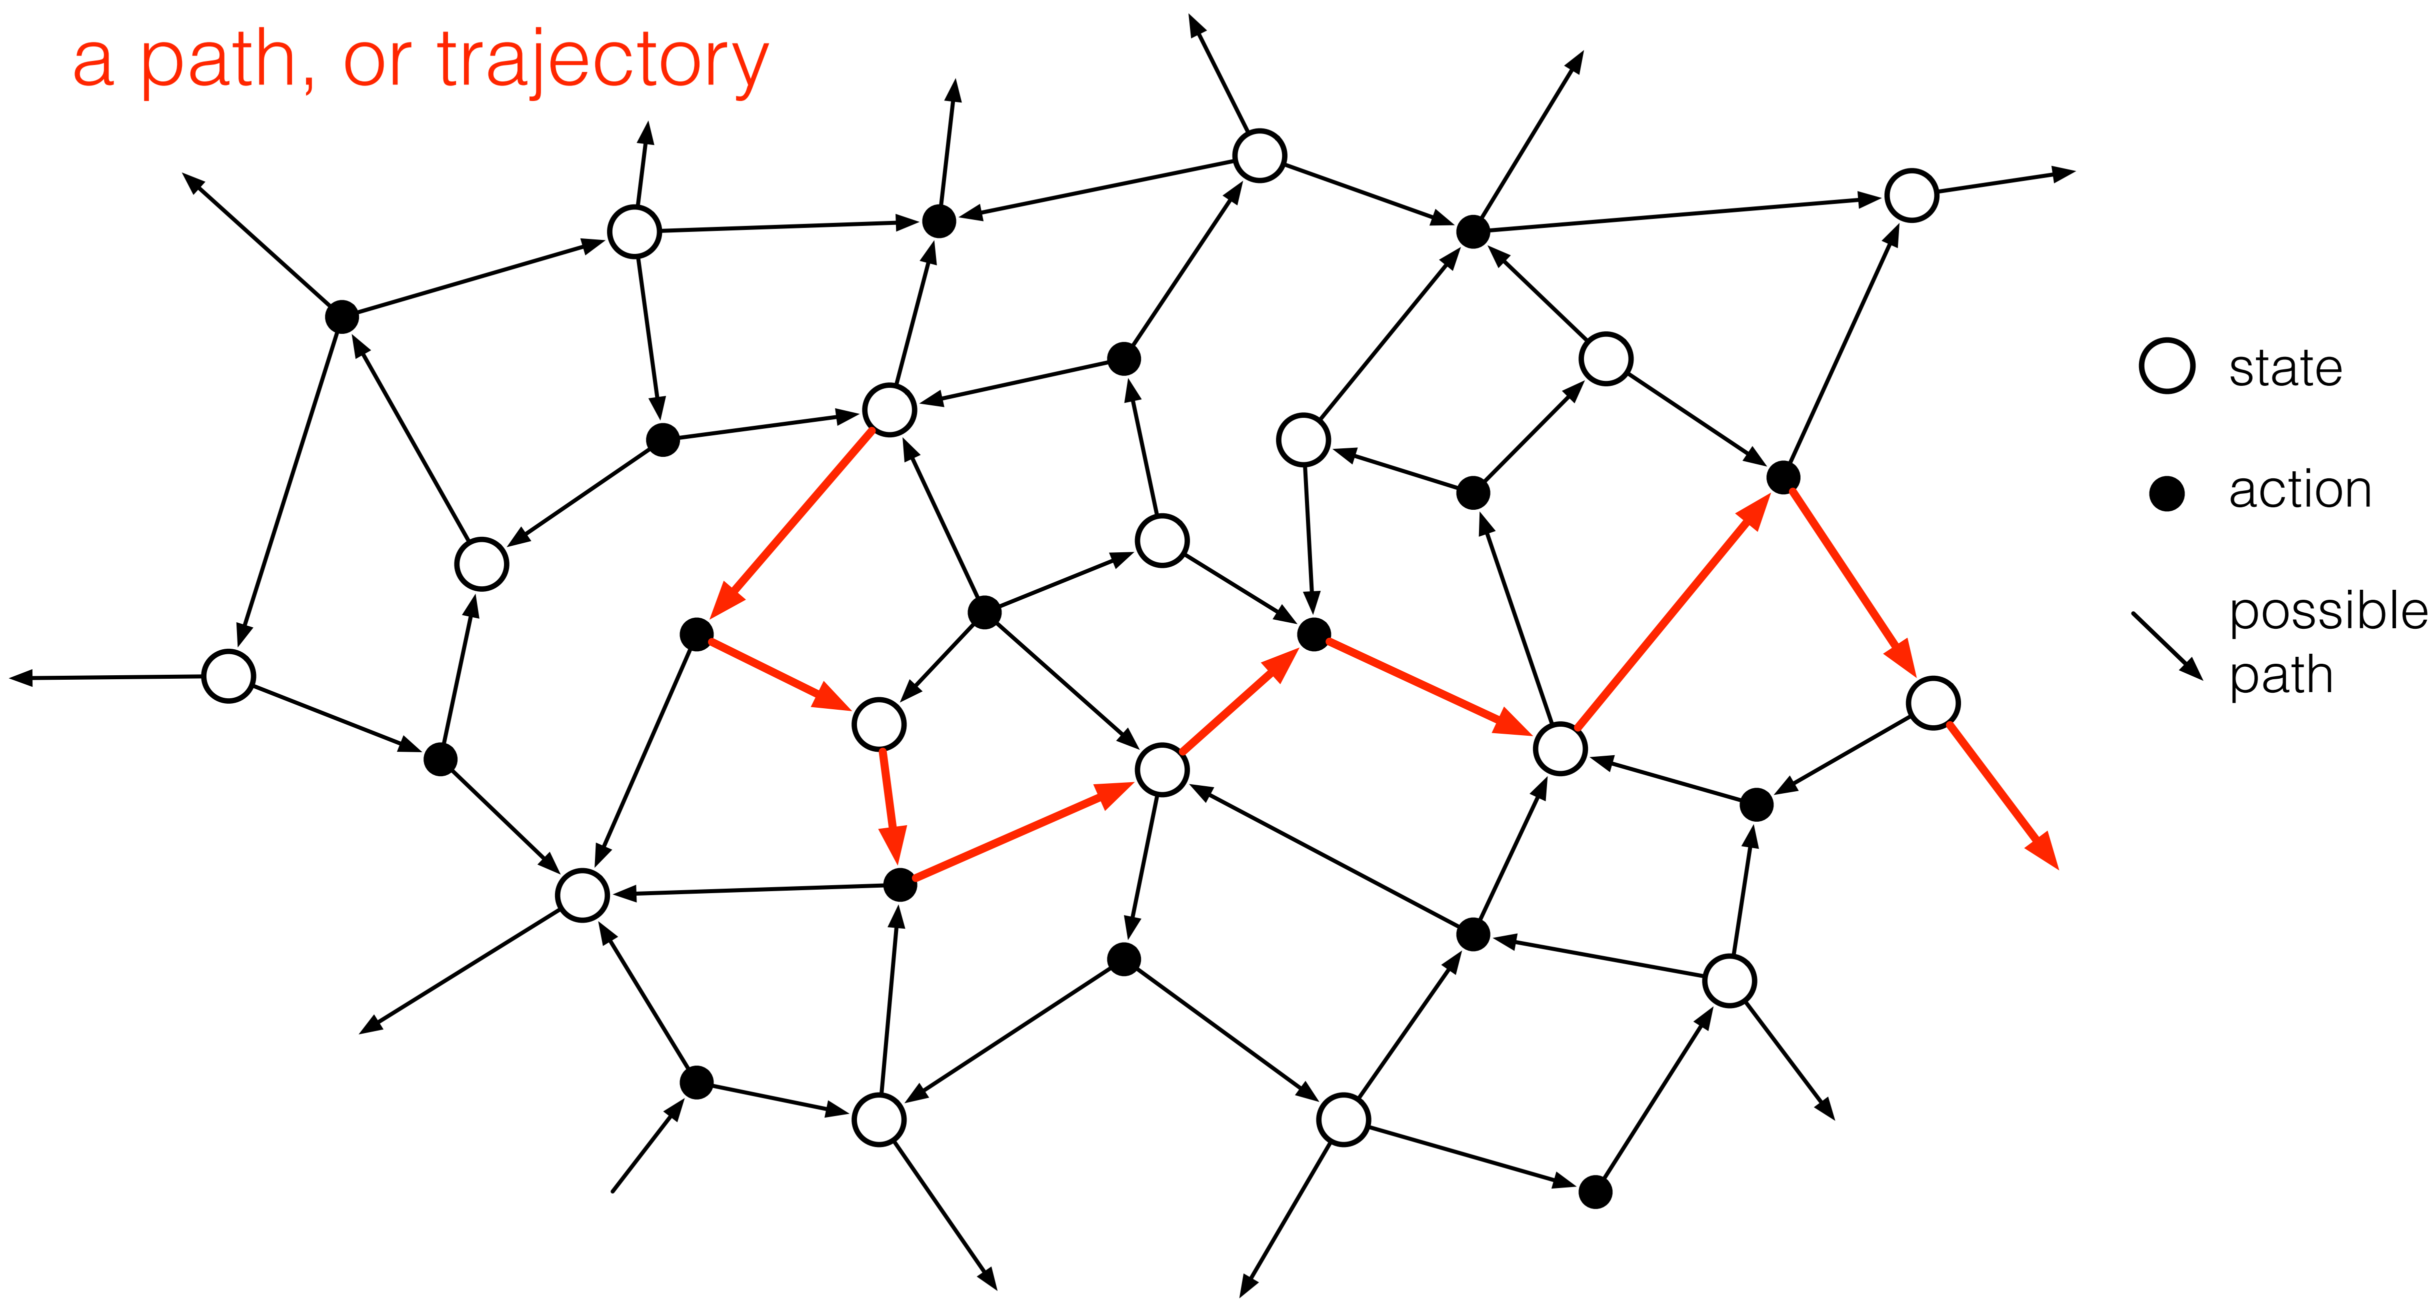
Bellman Equations

Recursive relationships among values
that can be used to compute values

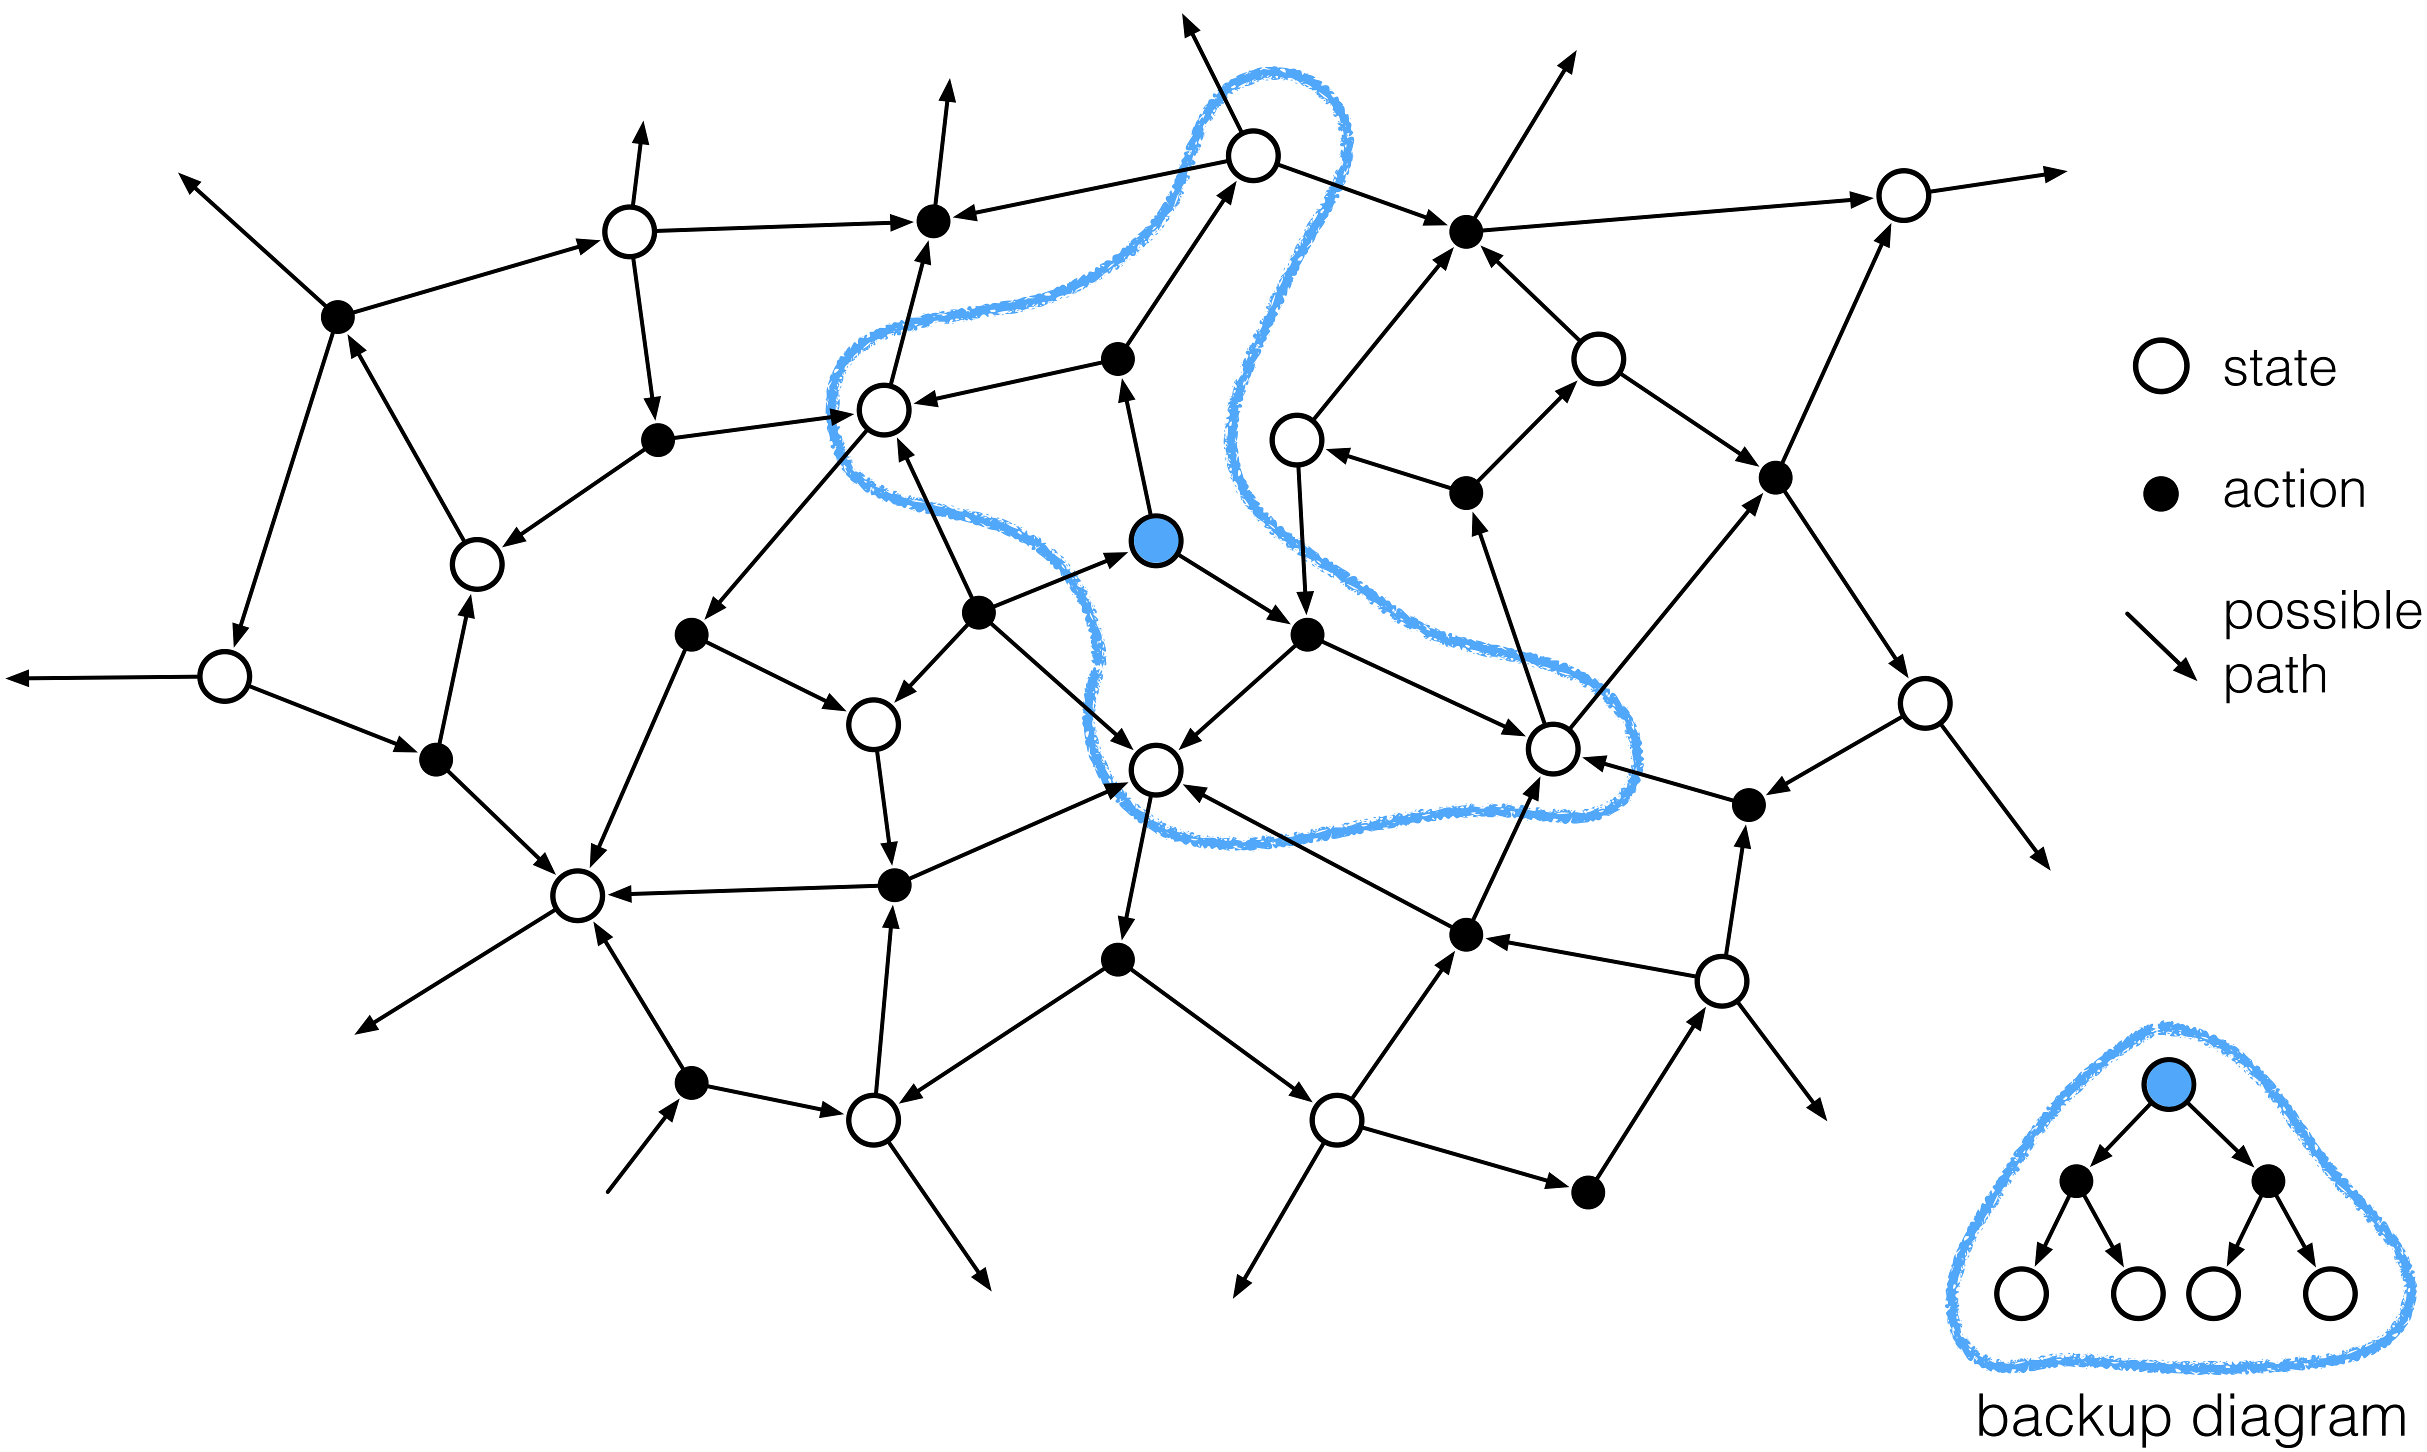
The tree of transition dynamics



The *web* of transition dynamics

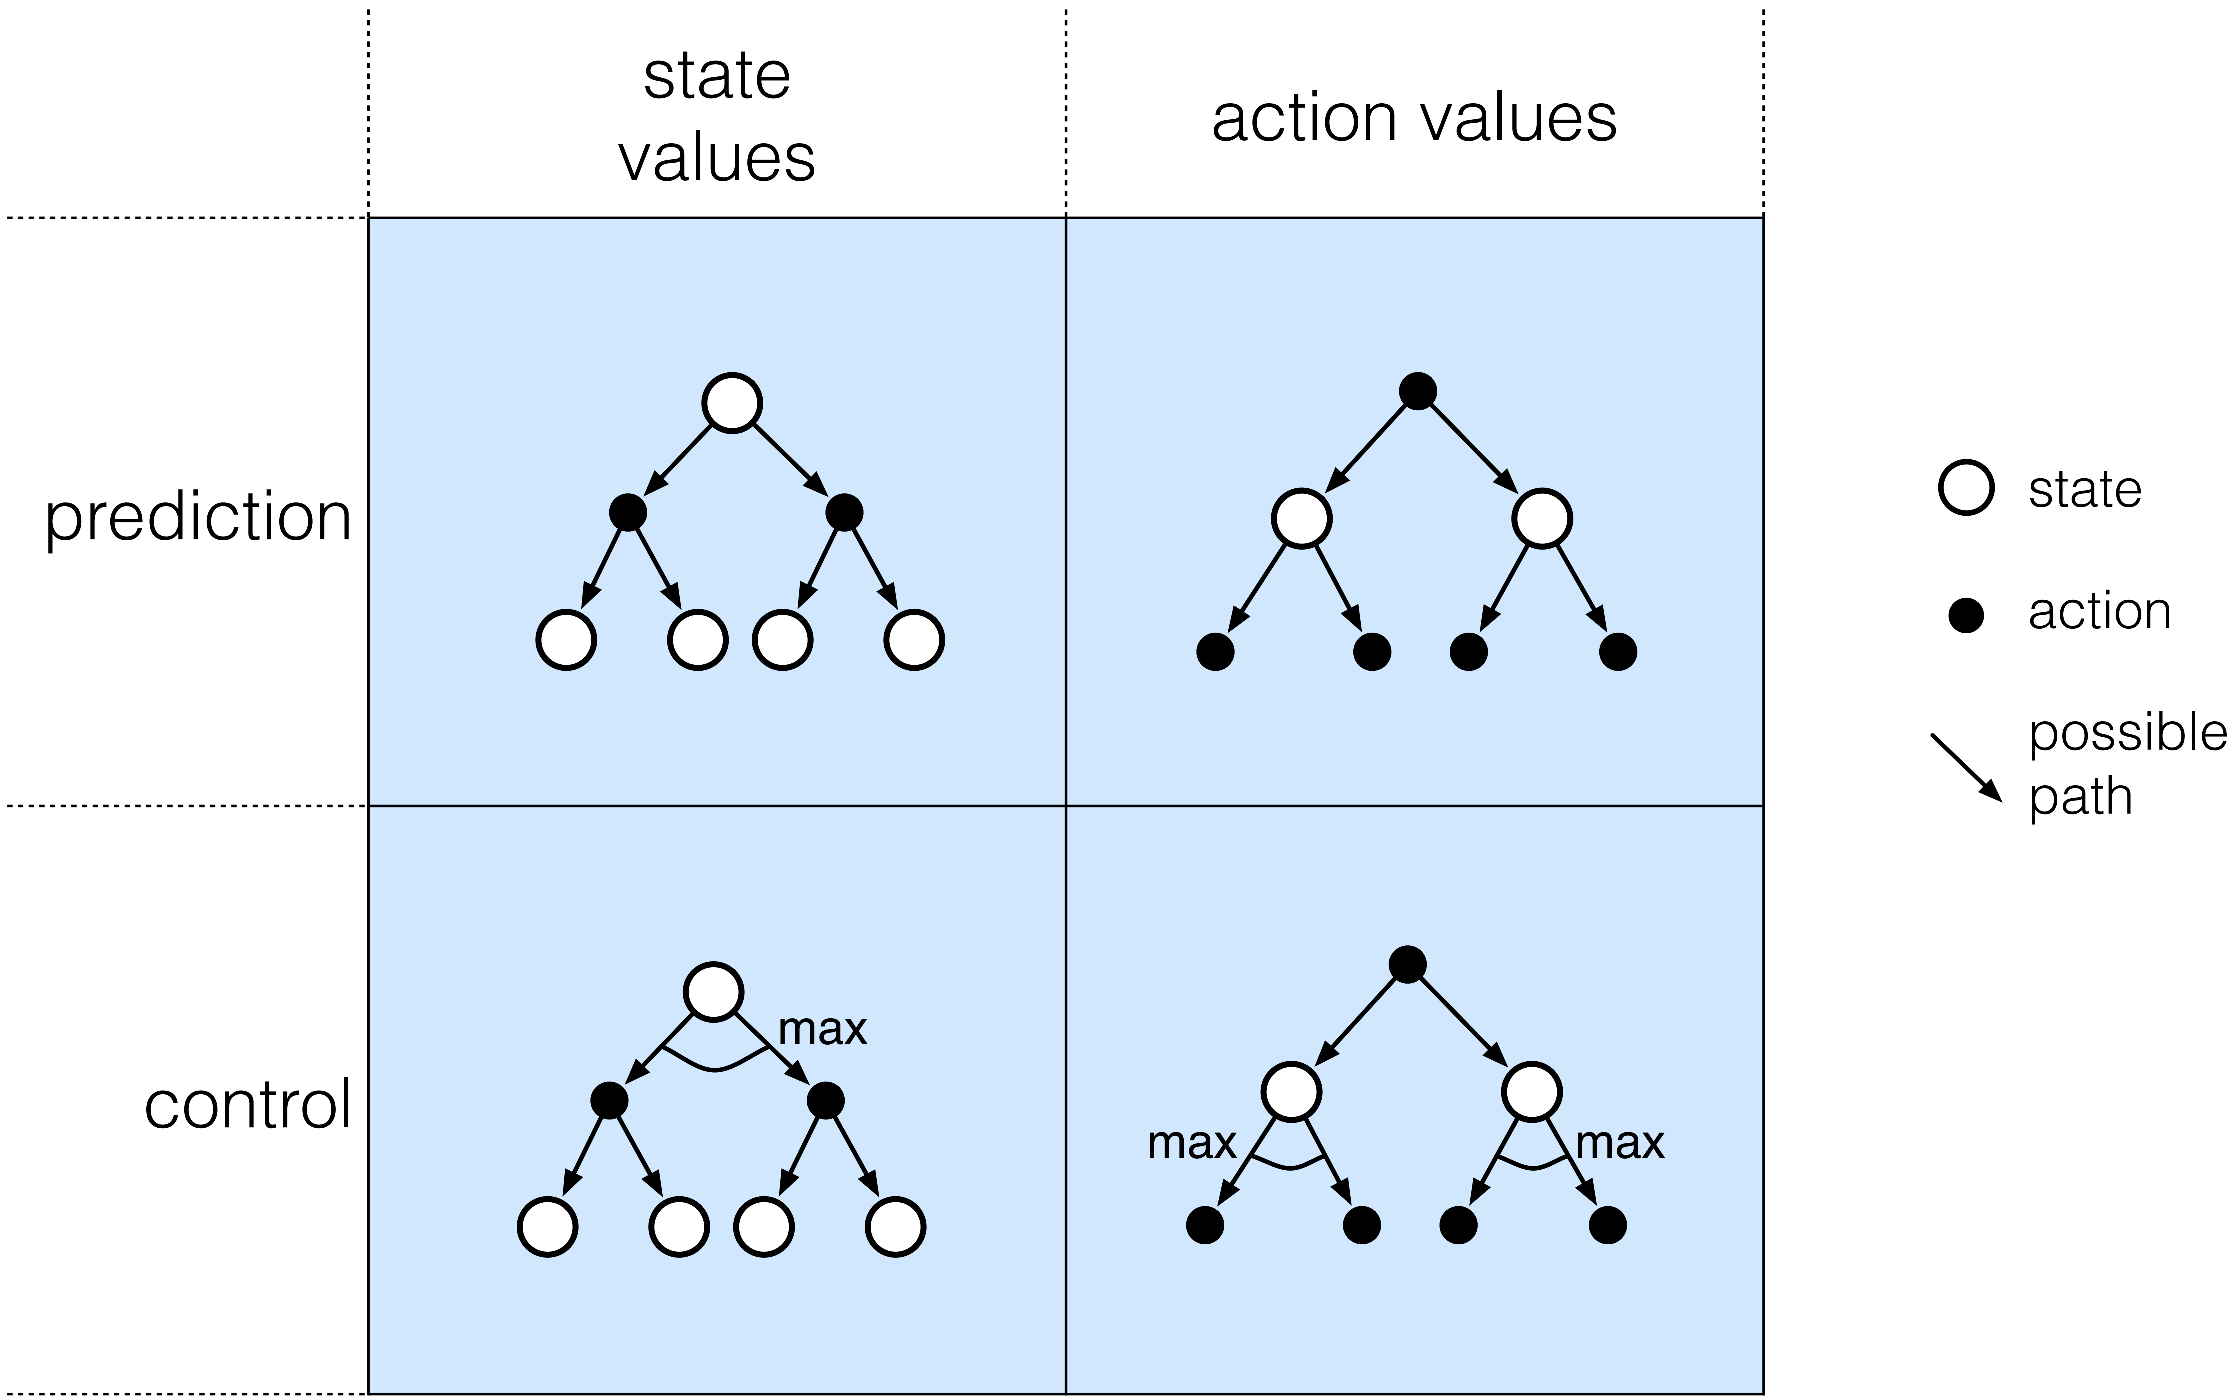


The *web* of transition dynamics



4 Bellman-equation backup diagrams

representing recursive relationships among values



Bellman Equation for a Policy π

The basic idea:

$$
\begin{aligned}
G_t &= R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \gamma^3 R_{t+4} + \cdots \\
&= R_{t+1} + \gamma \left(R_{t+2} + \gamma R_{t+3} + \gamma^2 R_{t+4} + \cdots \right) \\
&= R_{t+1} + \gamma G_{t+1}
\end{aligned}
$$

So:

$$
\boxed{
\begin{aligned}
v_\pi(s) &= E_\pi \left\{ G_t \mid S_t = s \right\} \\
&= E_\pi \left\{ R_{t+1} + \gamma v_\pi\left(S_{t+1}\right) \mid S_t = s \right\}
\end{aligned}
}
$$

Or, without the expectation operator:

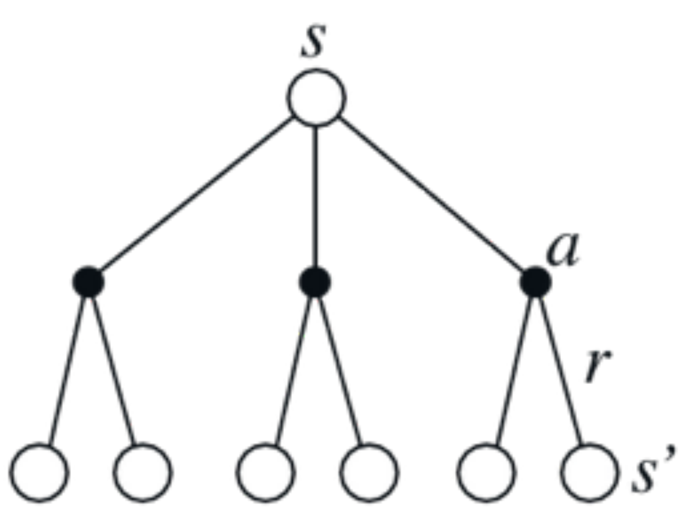
$$
v_\pi(s) = \sum_a \pi(a|s) \sum_{s',r} p(s', r|s, a) \Big[r + \gamma v_\pi(s') \Big]
$$

More on the Bellman Equation

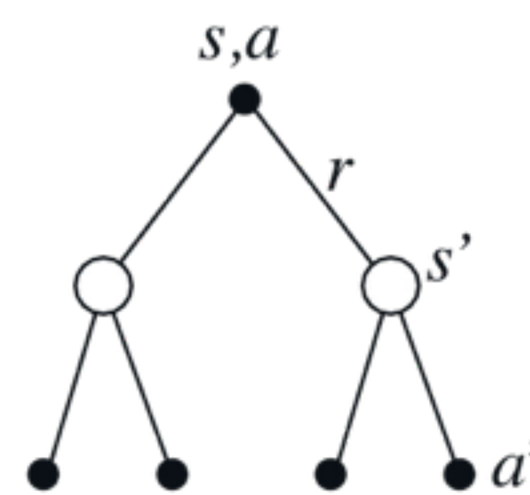
$$v_\pi(s) = \sum_a \pi(a|s) \sum_{s',r} p(s',r|s,a)\Big[r + \gamma v_\pi(s')\Big]$$

This is a set of equations (in fact, linear), one for each state.
The value function for π is its unique solution.

Backup diagrams:



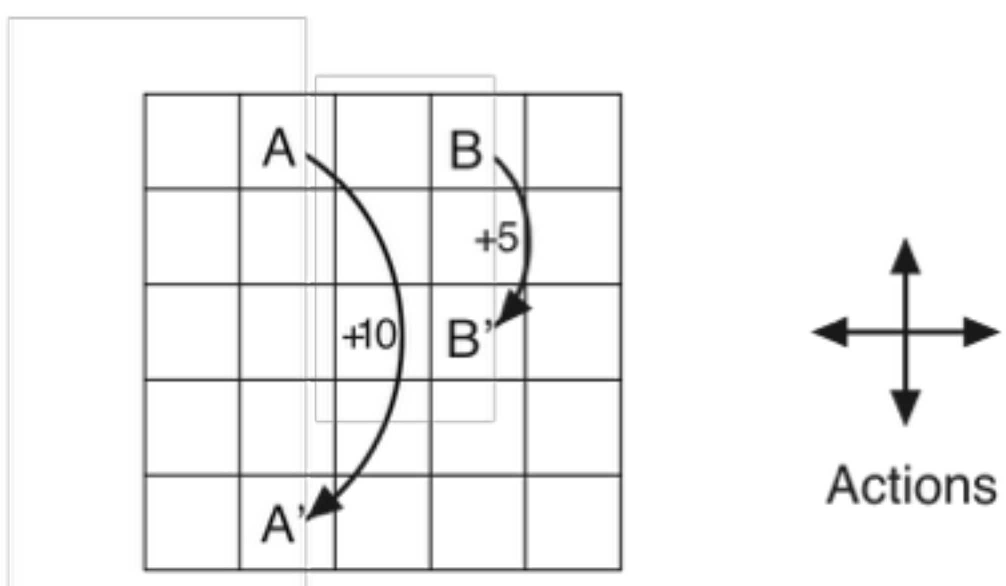
for v_π



for q_π

Gridworld

- Actions: `north`, `south`, `east`, `west`; deterministic.
- If would take agent off the grid: no move but reward = –1
- Other actions produce reward = 0, except actions that move agent out of special states A and B as shown.



(a)

3.3	8.8	4.4	5.3	1.5
1.5	3.0	2.3	1.9	0.5
0.1	0.7	0.7	0.4	-0.4
-1.0	-0.4	-0.4	-0.6	-1.2
-1.9	-1.3	-1.2	-1.4	-2.0

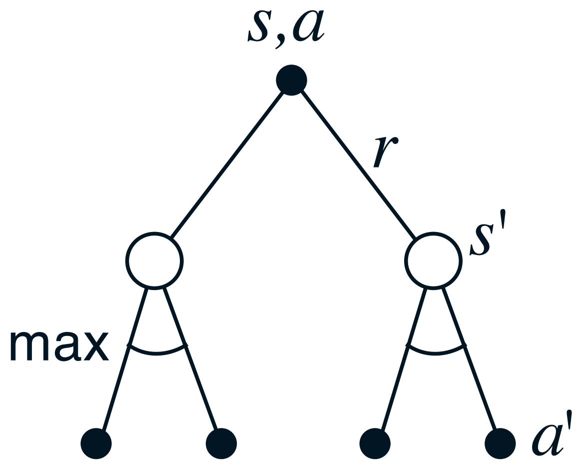
(b)

State-value function for equiprobable random policy; $\gamma = 0.9$

Bellman Optimality Equation for q_*

$$\begin{aligned} q_*(s,a) &= \mathbb{E}\Big[R_{t+1} + \gamma \max_{a'} q_*(S_{t+1}, a') \;\Big|\; S_t = s, A_t = a\Big] \\ &= \sum_{s',r} p(s', r|s,a)\Big[r + \gamma \max_{a'} q_*(s', a')\Big]. \end{aligned}$$

The relevant backup diagram:



q_* is the unique solution of this system of nonlinear equations.

Dynamic Programming

Using Bellman equations to compute values and optimal policies

(thus a form of planning)

Iterative Methods

$$v_0 \to v_1 \to \cdots \to v_k \to v_{k+1} \to \cdots \to v_\pi$$

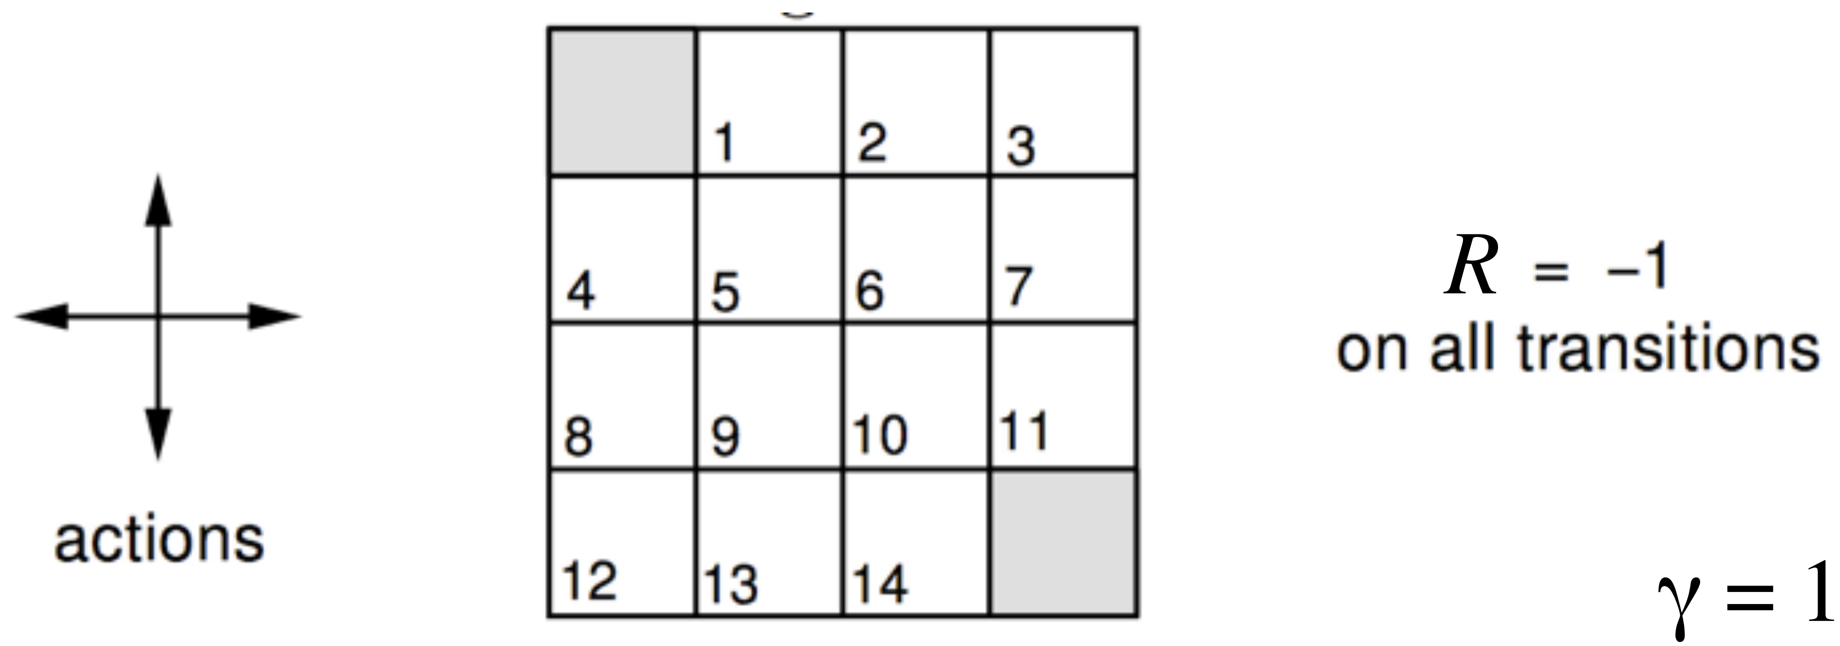
a "sweep"

A sweep consists of applying a **backup operation** to each state.

A **full policy-evaluation backup**:

$$v_{k+1}(s) = \sum_a \pi(a|s) \sum_{s',r} p(s',r|s,a)\Big[r + \gamma v_k(s')\Big] \qquad \forall s \in \mathcal{S}$$

A Small Gridworld



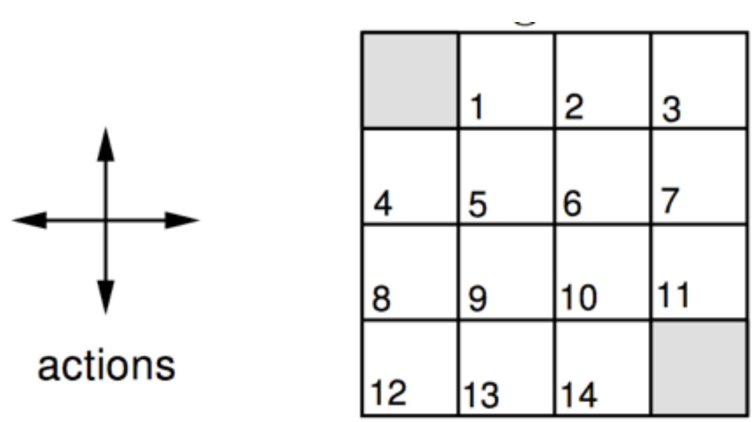
$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, . . ., 14;
- One terminal state (shown twice as shaded squares)
- Actions that would take agent off the grid leave state unchanged
- Reward is –1 until the terminal state is reached

Iterative Policy Eval for the Small Gridworld

V_k for the Random Policy

$\pi =$ equiprobable random action choices



$R = -1$ on all transitions

$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, . . ., 14;
- One terminal state (shown twice as shaded squares)
- Actions that would take agent off the grid leave state unchanged
- Reward is –1 until the terminal state is reached

$k = 0$

0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0

$k = 1$

0.0	-1.0	-1.0	-1.0
-1.0	-1.0	-1.0	-1.0
-1.0	-1.0	-1.0	-1.0

-6.1	-7.7	-8.4	-8.4
-8.4	-8.4	-7.7	-6.1
-9.0	-8.4	-6.1	0.0

$k = \infty$

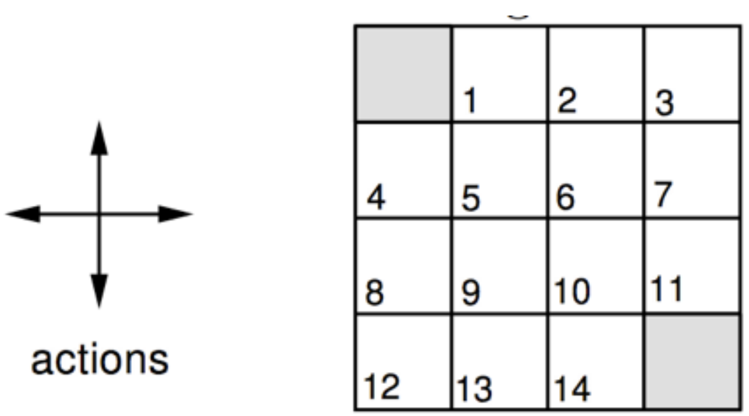
0.0	-14.	-20.	-22.
-14.	-18.	-20.	-20.
-20.	-20.	-18.	-14.
-22.	-20.	-14.	0.0

Iterative Policy Evaluation – One array version

Input π, the policy to be evaluated
Initialize an array $V(s) = 0$, for all $s \in \mathcal{S}^+$
Repeat
    $\Delta \leftarrow 0$
    For each $s \in \mathcal{S}$:
        $v \leftarrow V(s)$
        $V(s) \leftarrow \sum_a \pi(a|s) \sum_{s',r} p(s', r|s, a)\big[r + \gamma V(s')\big]$
        $\Delta \leftarrow \max(\Delta, |v - V(s)|)$
until $\Delta < \theta$ (a small positive number)
Output $V \approx v_\pi$

Iterative Policy Eval for the Small Gridworld

$\pi =$ equiprobable random action choices



$R = -1$
on all transitions

$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, . . ., 14;
- One terminal state (shown twice as shaded squares)
- Actions that would take agent off the grid leave state unchanged
- Reward is –1 until the terminal state is reached

V_k for the Random Policy

$k = 0$

0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0
0.0	0.0	0.0	0.0

$k = 1$

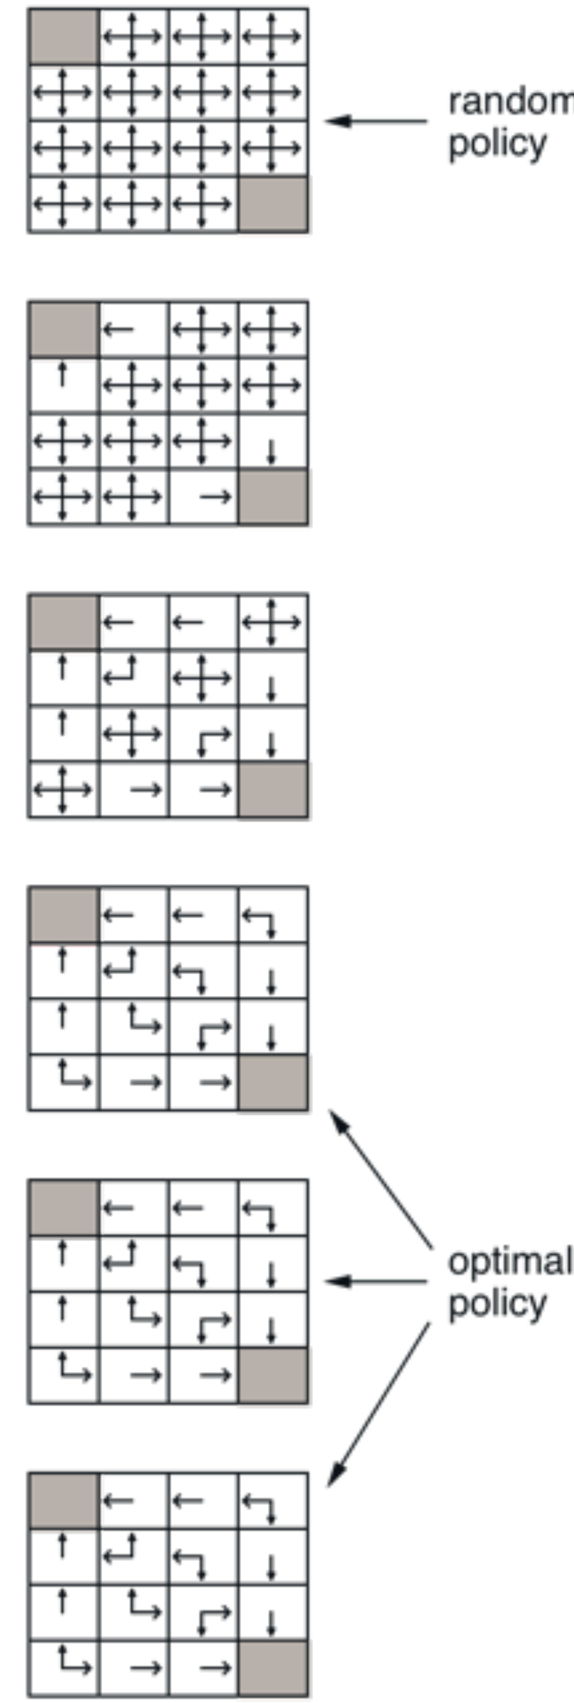
-9.0	-8.4	-6.1	0.0

$k = \infty$

0.0	-14.	-20.	-22.
-14.	-18.	-20.	-20.
-20.	-20.	-18.	-14.
-22.	-20.	-14.	0.0

Greedy Policy w.r.t. V_k

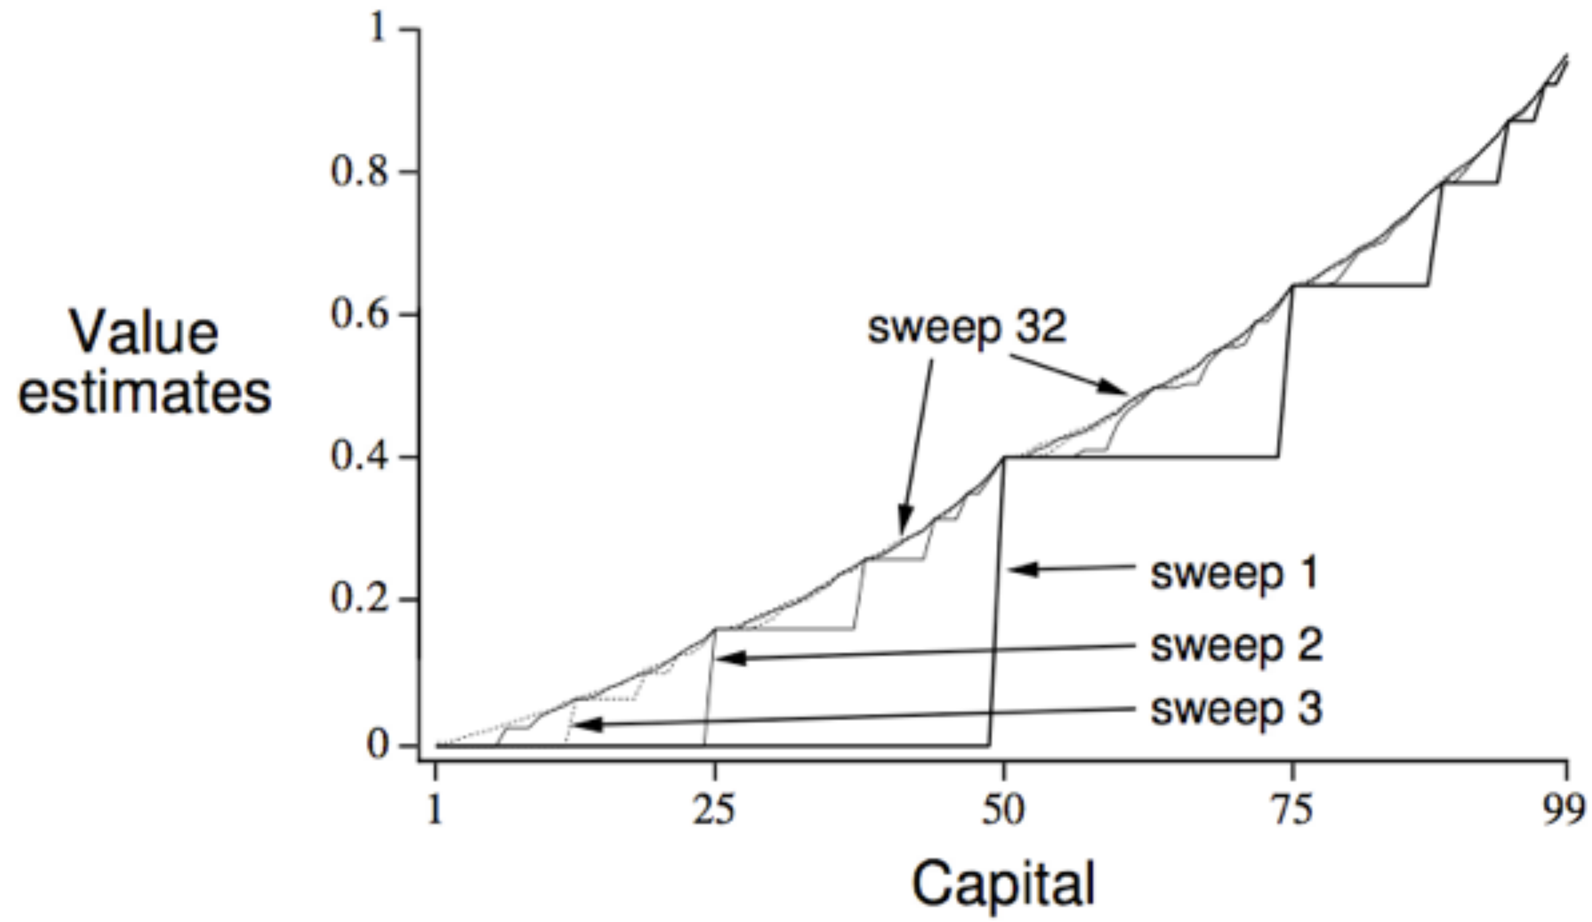


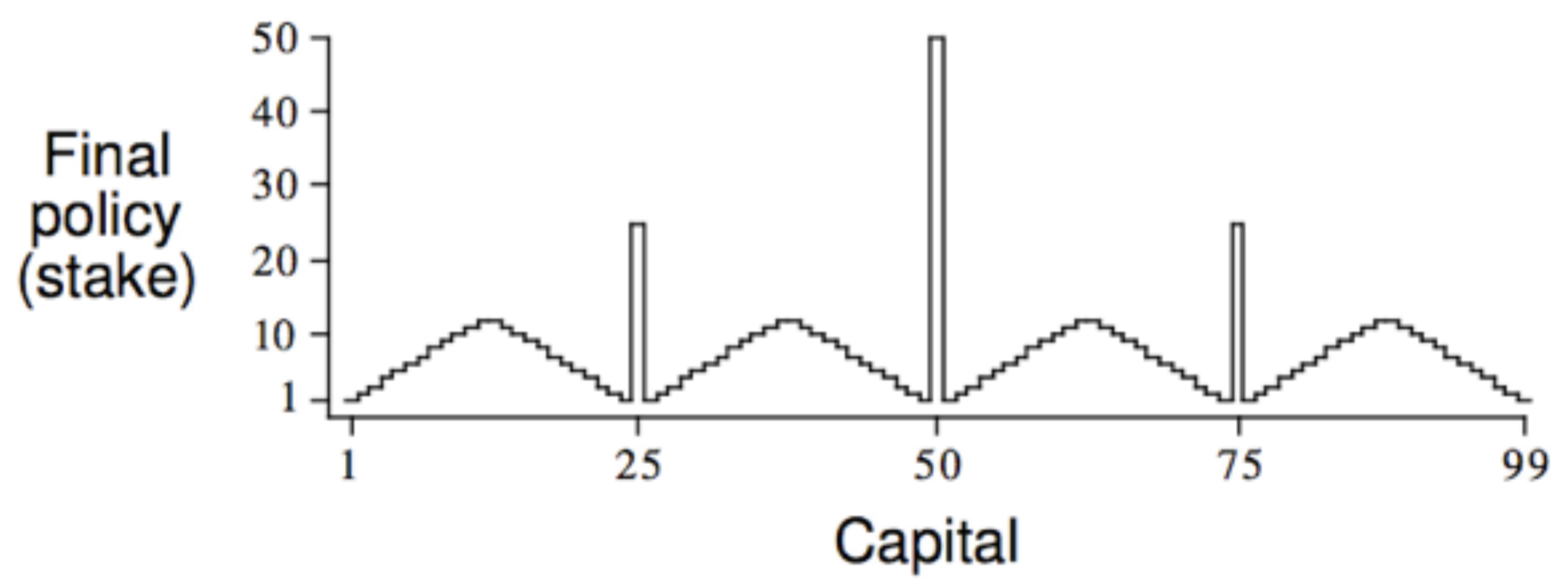
Gambler's Problem

- Gambler can repeatedly bet \$ on a coin flip
- Heads he wins his stake, tails he loses it
- Initial capital $\in$ {\$1, \$2, … \$99}
- Gambler wins if his capital becomes \$100
  loses if it becomes \$0
- Coin is unfair
  - Heads (gambler wins) with probability p = .4

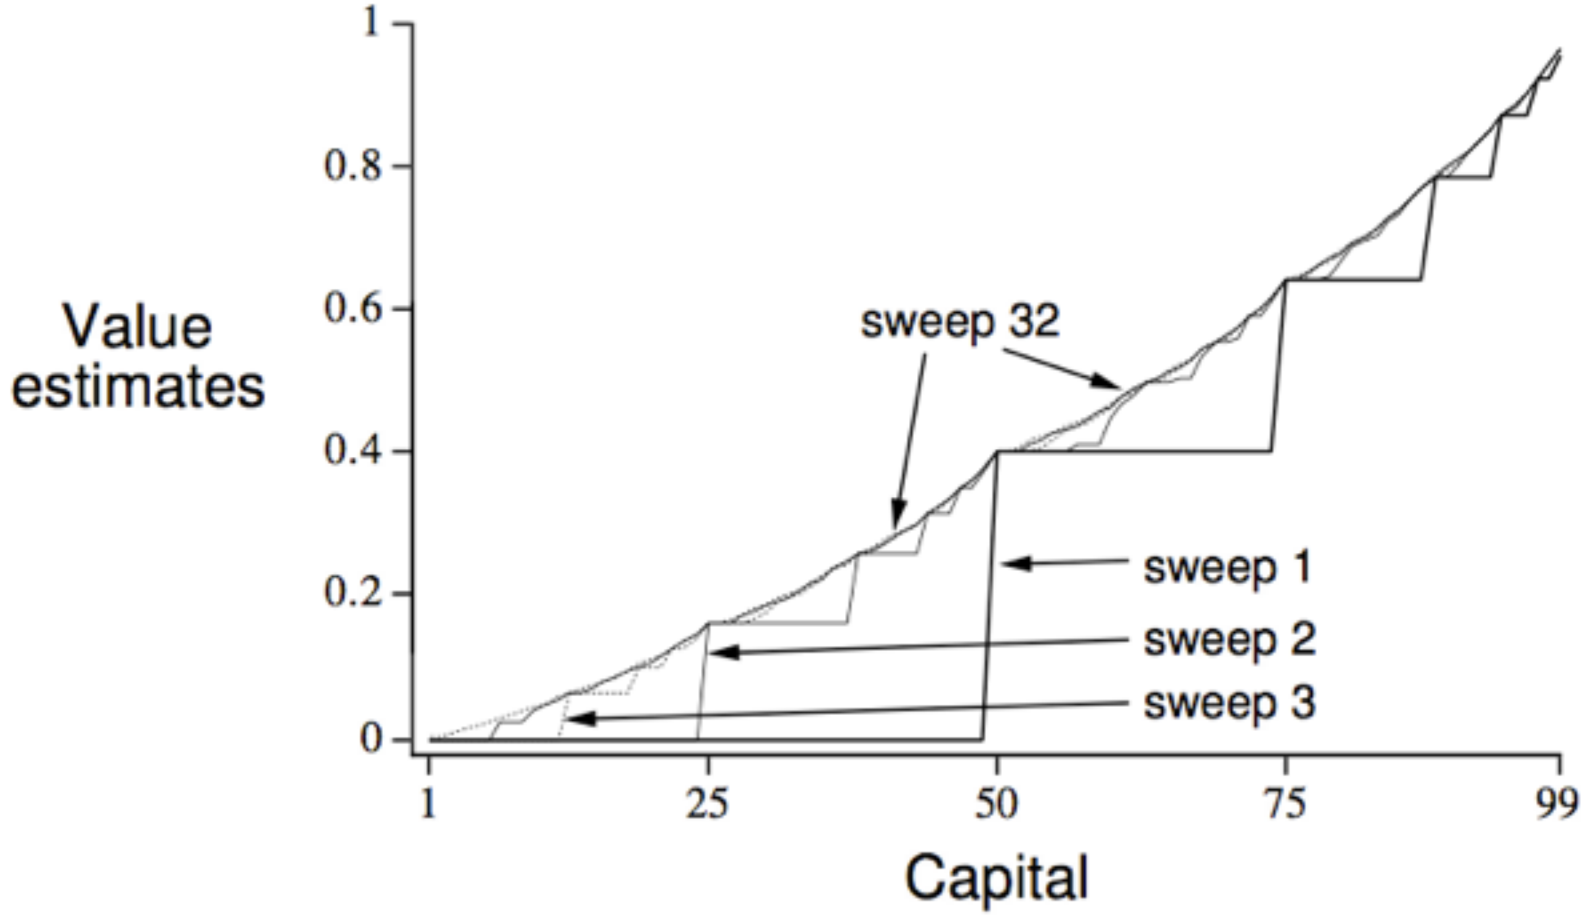
- States, Actions, Rewards?

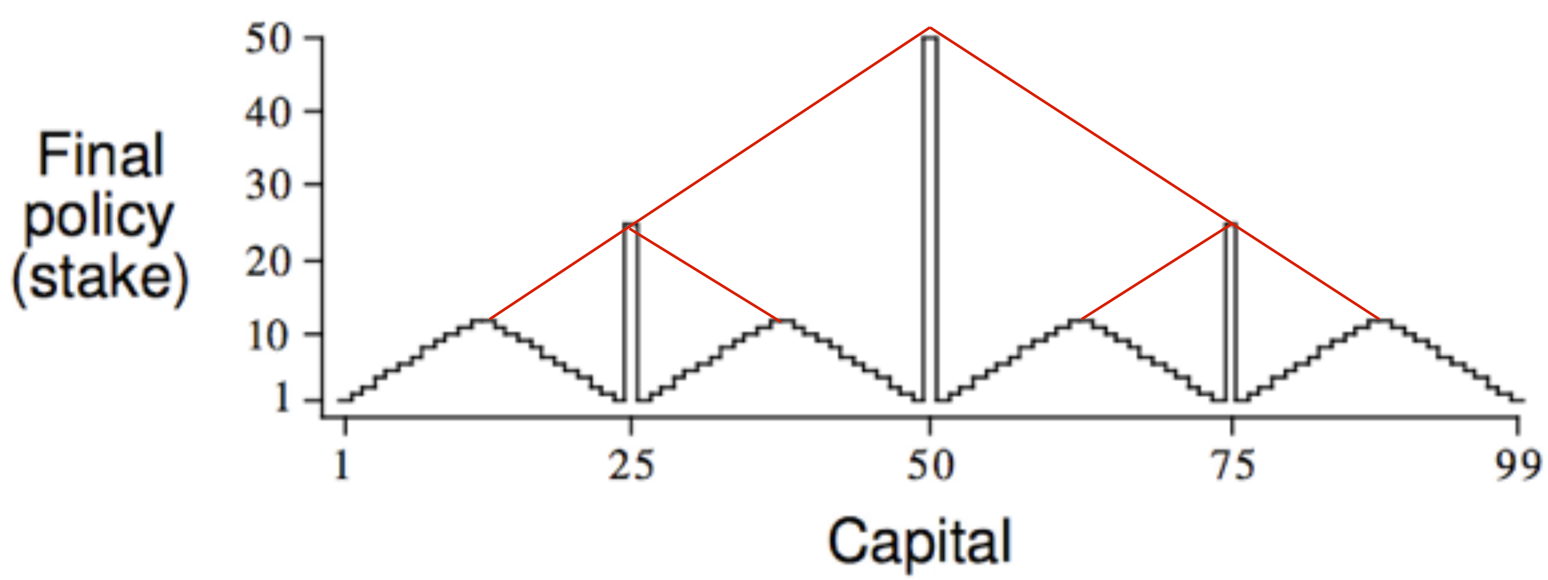
Gambler's Problem Solution





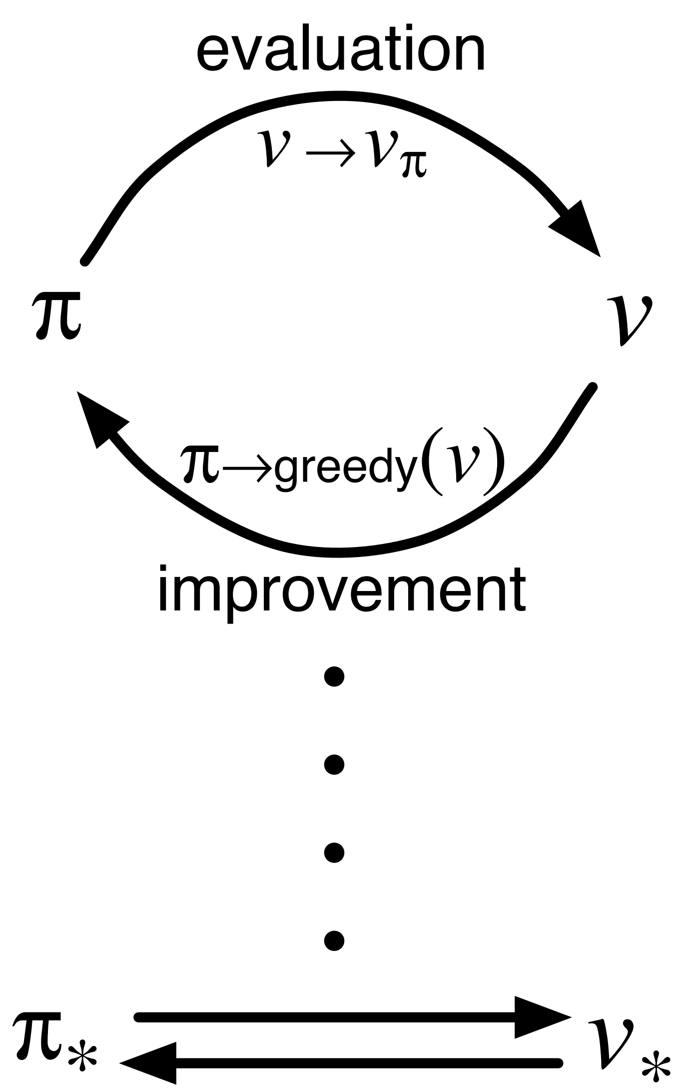
Gambler's Problem Solution



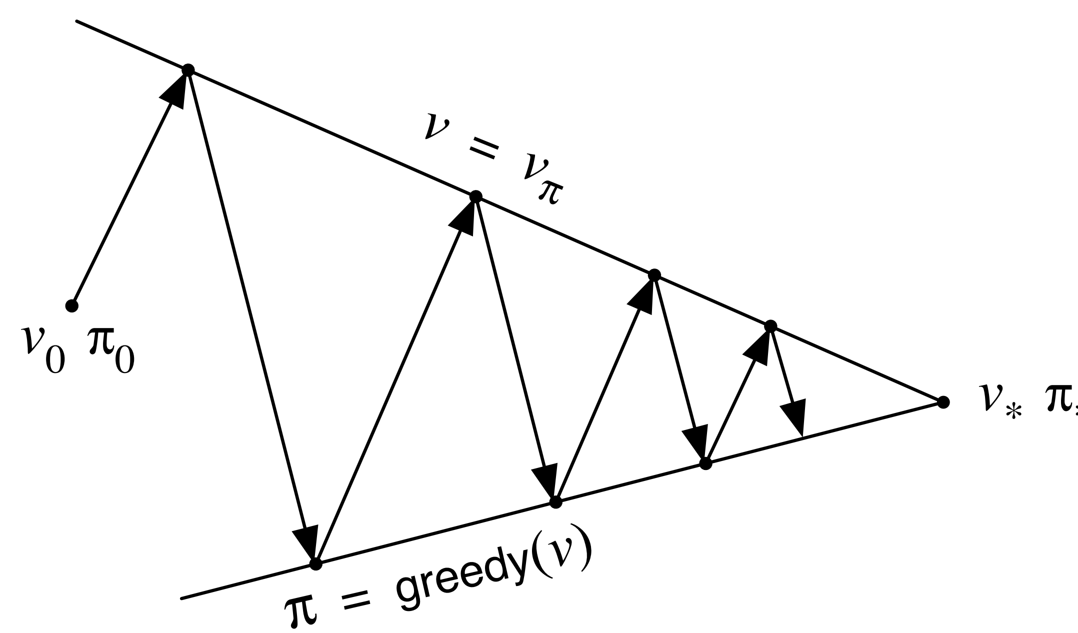


Generalized Policy Iteration

Generalized Policy Iteration (GPI):
any interaction of policy evaluation and policy improvement, independent of their granularity.



A geometric metaphor for convergence of GPI:

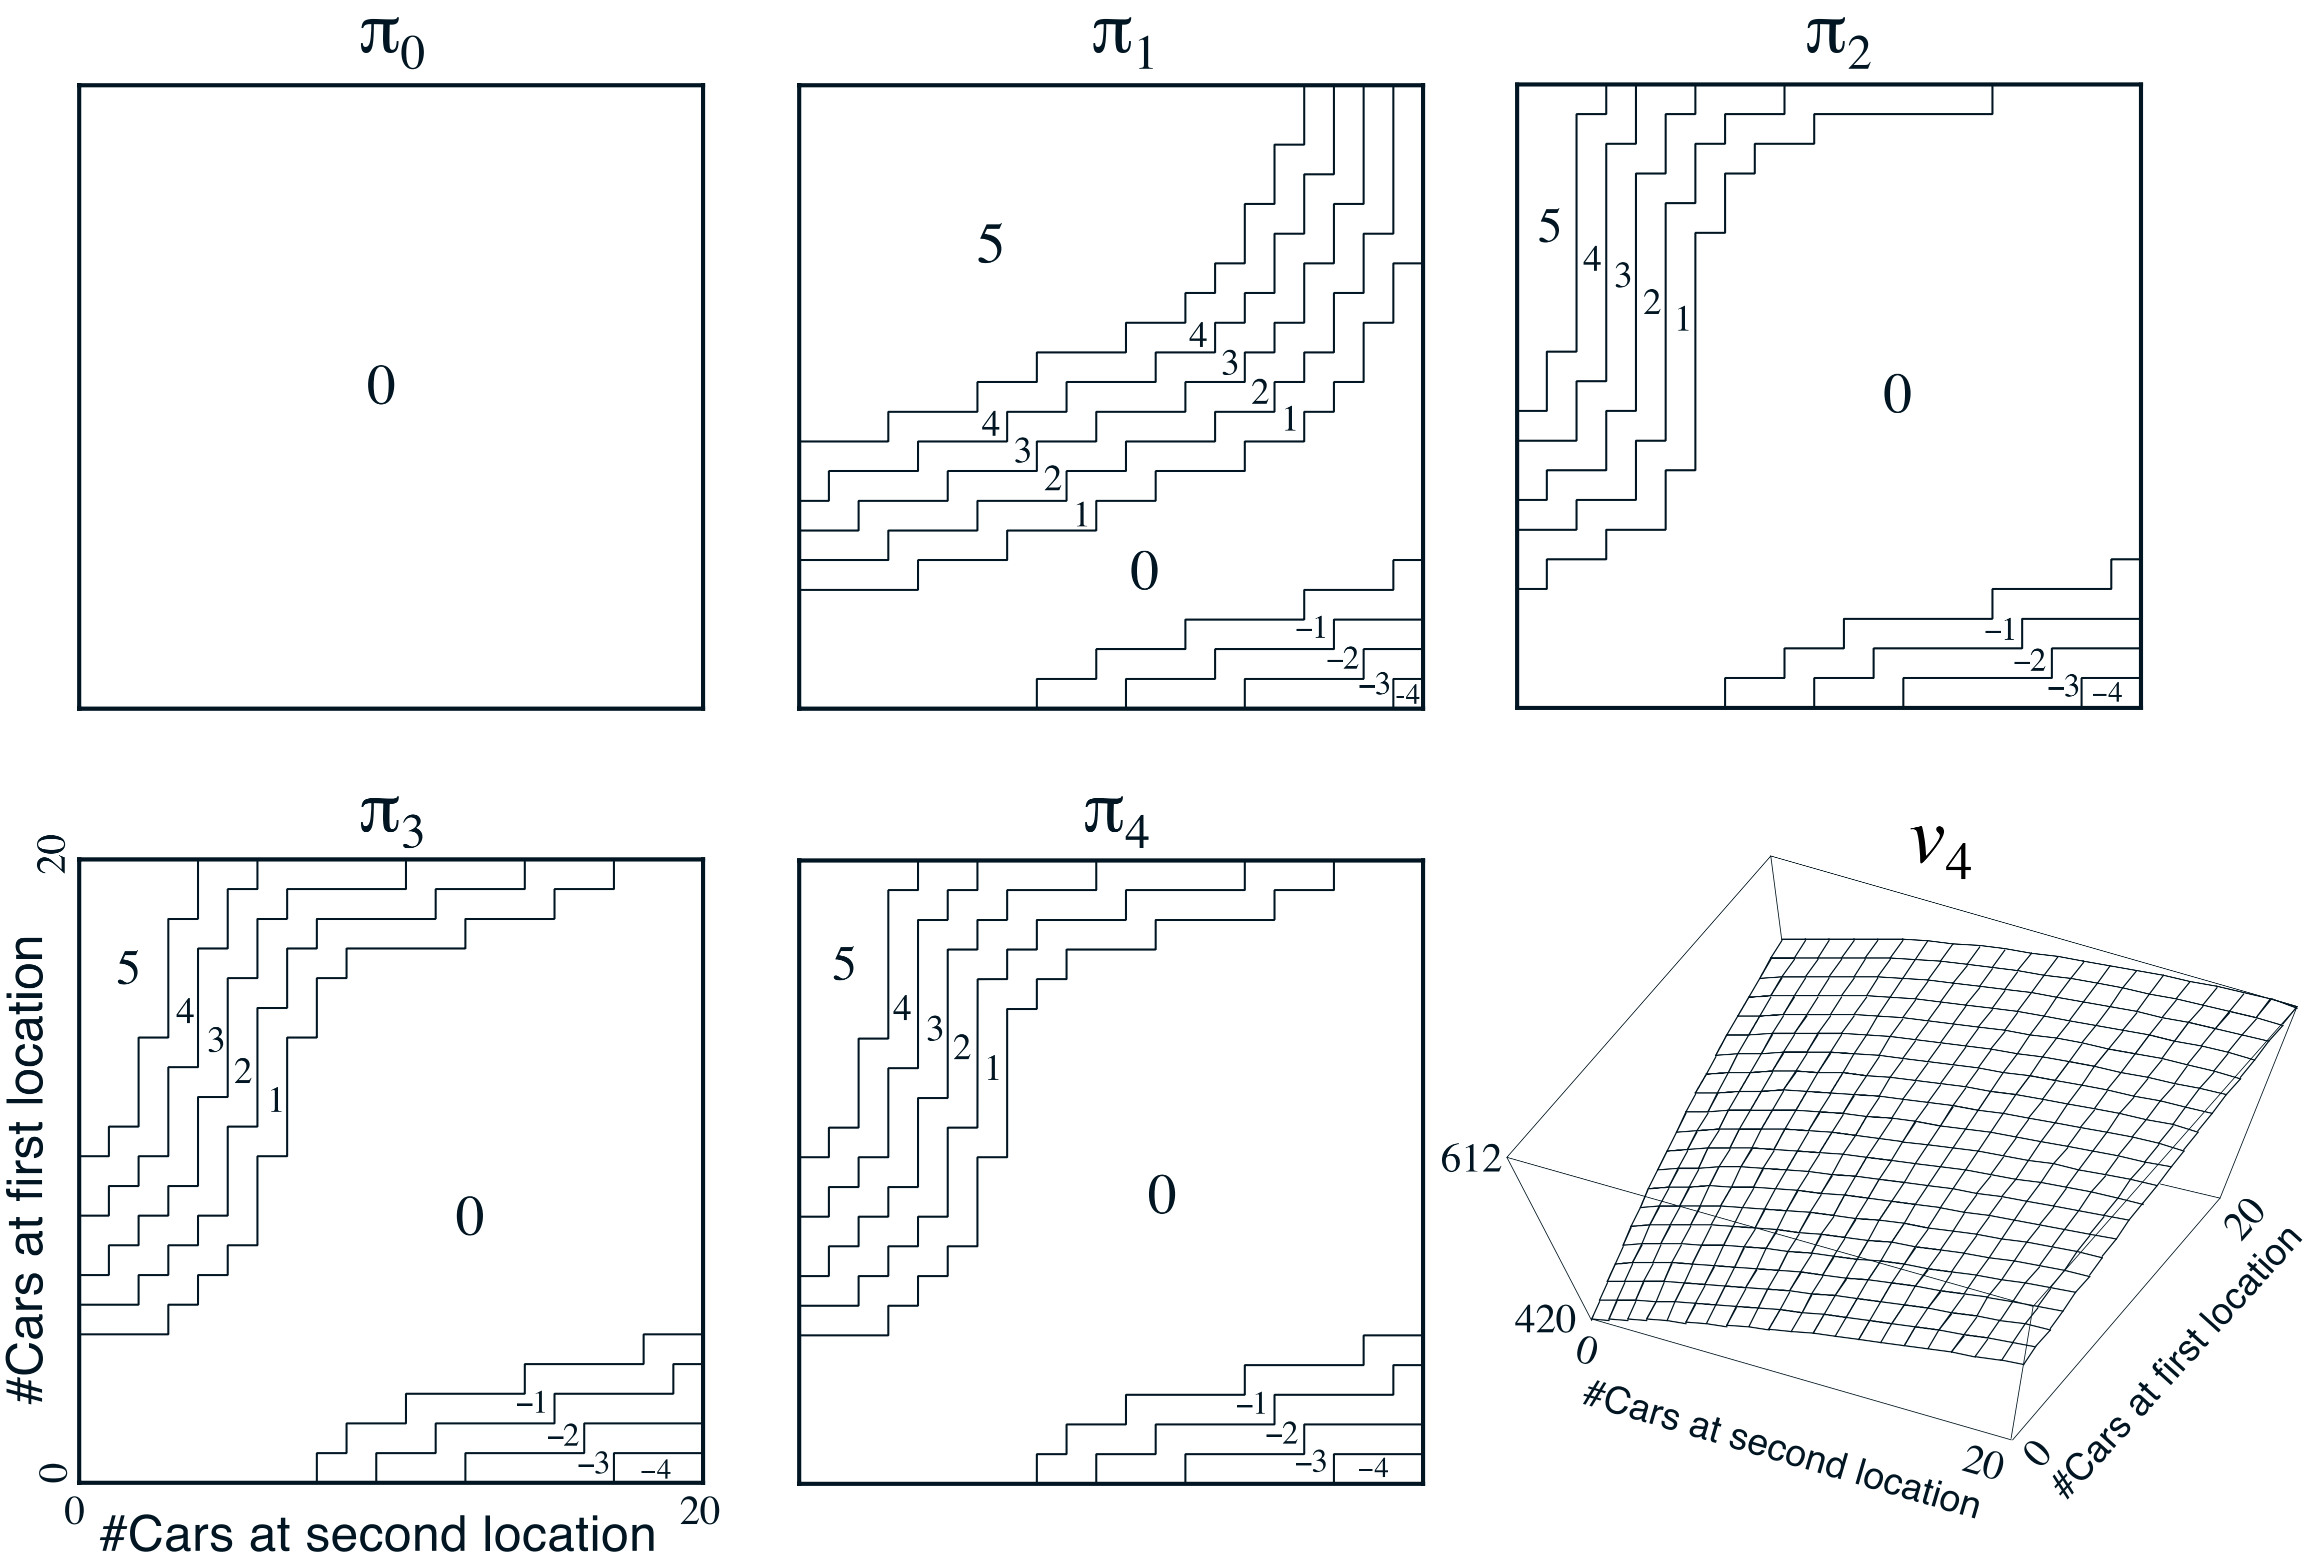


Jack's Car Rental

- $10 for each car rented (must be available when request rec'd)
- Two locations, maximum of 20 cars at each
- Cars returned and requested randomly
  - Poisson distribution, n returns/requests with prob $\frac{\lambda^n}{n!}e^{-\lambda}$
  - 1st location: average requests = 3, average returns = 3
  - 2nd location: average requests = 4, average returns = 2
- Can move up to 5 cars between locations overnight

- States, Actions, Rewards?
- Transition probabilities?

Jack's Car Rental



Solving MDPs with Dynamic Programming

- Finding an optimal policy by solving the Bellman Optimality Equation requires the following:
  - accurate knowledge of environment dynamics;
  - we have enough space and time to do the computation;
  - the Markov Property.
- How much space and time do we need?
  - polynomial in number of states (via dynamic programming methods; Chapter 4),
  - BUT, number of states is often huge (e.g., backgammon has about 10^{20} states).
- We usually have to settle for approximations.
- Many RL methods can be understood as approximately solving the Bellman Optimality Equation.

Efficiency of DP

- To find an optimal policy is polynomial in the number of states…
- BUT, the number of states is often astronomical, e.g., often growing exponentially with the number of state variables
- We need to use approximation, but unfortunately classical DP is not sound with approximation (later)
- In practice, classical DP can be applied to problems with a few millions of states.
- It is surprisingly easy to come up with MDPs for which DP methods are not practical.
- Biggest limitation of DP is that it requires a *probability model* (as opposed to a generative or simulation model)
